INTRODUCTION

This document describes the specifications and methods for the implementation of the "AML-Scan Tool" service which will be based on the "Regulat.io" application (<https://app.regulat.io>) of the company MAQIT S.A.

OBJECTIVES

The "AML-Scan Tool" service will offer the customer the possibility to automatically fill in the questionnaires relating to the anti-money laundering profiling of the individual subject of verification (natural person or legal entity).

DESCRIPTION

A button called "**Check in Global Watchlist**" should be set up in the form-views of "*Surveys*", "*Verifications*" and "*Sections*" only if the following conditions are blown:

- the user must be enabled for the service;
- The survey refers to a service-specific verification model ;

When the button is pressed, a REST API call will start that will query Regulat.io and based on the answer will launch a PostgreSQL function that will compile the questions.

For each scan , the personal data connected to the personal data subject to the verification must first be identified. These personal data, in addition to the main one, will have to be scanned in turn.

PARAMETERS

The parameters necessary for full operation are:

- Type (natural person or legal person)
- Name (company name in the case of a legal entity)
- Surname (only in the case of a natural person)
- Age (only in the case of a natural person)
- Company Code
- Administration
- Survey (I deduce it from administration)
- Verification template ID (I deduce it from survey)
- Version of the verification template (I deduce it from survey)

TECHNICAL NOTES

Profiles (profiles.schema.json)

Addgere "kyctech" under items/properties/source/enum.

```
"externalSources": {
  "type": "array",
  "description": "?: set of tables on which to enable data import from external source",
  "items": {
    "type": "object",
    "additionalProperties": false,
    "required": [
      "entry",
      "source"
    ],
    "properties": {
      "entry": {
        "type": "string",
        "description": "M: name of the affected table"
      },
      "source": {
        "type": "string",
        "description": "M: external data source",
        "enum": [
          "archiflow",
          "kyctech"
        ]
      }
    }
  }
}
```

Test Profile (admin_test_kyctech.json)

Add the chosen form entries to host the service under "externalSources".

```
{
  "$schema": "../profiles.schema.json",
  "menu": {
    "allow": [
      "*"
    ],
    "deny": []
  },
  "name": "admin_test_kyctech",
  "tables": {
    "allow": [
      "*"
    ],
    "deny": [],
    "form_keys": [],
    "readOnly": [],
    "table_keys": [],
    "queryCond": [],
    "externalSources": [
      {
        "entry": "surveys",
        "source": "kyctech"
      },
      {
        "entry": "sondaggi_somministrati",
        "source": "kyctech"
      },
      {
        "entry": "domande_sezioni_sub_of_somministrazioni",
        "source": "kyctech"
      }
    ]
  }
}
```

Button and click function (on dynamic-form.component)

Add in the sheet .html under </ng-container> the "Check in Global Watchlist" button

```
<form style="margin-left: 1%; margin-right: 1%; width: 98%; margin-bottom: 1%; margin-top: 1%;"
[style.background-color] ="isQuickAdd? 'transparent': 'whitesmoke'" class='p-0 mat-elevation-z2 dynamic-form'
[formGroup] = 'form' [id]='formName' (submit)='onSubmit($event)'>
<ng-container *ngFor='let field of fields; ' dynamicField [field]='field' [group]='form'
[readOnlyPage] ='readOnlyPage'>
</ng-container>

<button *ngIf="showKycTechButton" mat-button (click)="kycTech()">
<mat-icon>update</mat-icon>
Check in Global Watchlist
</button>

</form>
```

Add to the sheet .ts something like the following, and create the associated lambda function in which I will call another lambda to "exit" the vpc

```
kycTech() {
const _this = this;
at the moment we only handle Archiflow import
if (_this.importDataSource === 'kyctech') {
_this._dialogService.showLoadingDialog('Connecting to Regulat.io', 'Please wait...');
_this.subscriptions.push(_this.backendService.KycTech(0).subscribe( get the number of records
result => {
_this._console.log(result);
_this._dialogService.closeDialog();
_this._dialogService.showLoadingDialog('Retrieving records from Regulat.io', 'Please wait...');
if (result.result === 'OK') {
_this.subscriptions.push(_this.backendService.KycTech(result.numRecords).subscribe(
innerResult => {
_this._console.log(innerResult);
if (innerResult.result === 'OK') {
_this.loadData();
_this._dialogService.closeDialog();
_this._toastService.showSuccessToast('Successfully updated! '); show success toast
} else {
_this._dialogService.closeDialog();
_this._toastService.showErrorToast('An error occurred! ');
}
},
innerError => {
_this._dialogService.closeDialog();
_this._toastService.showErrorToast('An error occurred! ');
}
));
} else {
```

```
_this._dialogService.closeDialog();
_this._toastService.showErrorToast('An error occurred!');
},
error => {
_this._dialogService.closeDialog();
_this._toastService.showErrorToast('An error occurred!');
});
}
```

DB PostgreSQL

Create tables dedicated to the answer under the imports scheme and create automatic questionnaire compilation function based on the answer.

REST API Call and Answer

Refer to the postman collection: <https://www.getpostman.com/collections/1523eb204a5eb9866739>

In this collection there is the generation of an access token (**Auth/token**) and the two different calls (person **api/kyc/v1/person** or company **api/kyc/v1/company**) in addition to the call that returns the number of scans made (**api/kyc/v1/scans**).
